#### INTERIM REPORT

#### **BIOVENTING FIELD INITIATIVE**

#### WESTOVER AIR FORCE BASE, MASSACHUSETTS

#### 1.0 INTRODUCTION

This report describes the activities conducted at Westover Air Force Base (AFB), Massachusetts, as part of the Bioventing Field Initiative for the U.S. Air Force Center for Environmental Excellence (AFCEE) and the Environics Directorate of the Air Force Armstrong Laboratory. This report summarizes the results from the first phase of the study at Westover AFB. First-phase activities include a soil gas survey, air permeability test, in situ respiration test, and installation of bioventing systems. The specific objectives of this Bioventing Field Initiative are described in the following section. The test site at the base is discussed individually, followed by a description of site activities at the background area.

#### 1.1 Objectives

The purpose of this Bioventing Field Initiative is to measure the soil gas permeability and microbial activity at a contaminated site in order to evaluate the potential application of bioventing technology to remediate the site. The specific test objectives are stated below.

- A small-scale soil gas survey will be conducted to identify an appropriate
  location for installation of the bioventing system. Soil gas from the candidate
  site should exhibit high total petroleum hydrocarbon (TPH) concentrations,
  relatively low oxygen concentrations, and relatively high carbon dioxide
  concentrations. An uncontaminated background location also will be
  identified.
- The soil gas permeability of the soil and the air vent (well) radius of influence will be determined. To measure these parameters, air will be withdrawn or injected for approximately 8 hours at vent wells located in contaminated soils. Pressure changes will be monitored in an array of monitoring points.
- Immediately following the soil gas permeability test, an in situ respiration test will be conducted. Air will be injected into selected monitoring points to

aerate the soils. The in situ oxygen utilization and carbon dioxide production rates will be measured.

• The data from the soil gas permeability and in situ respiration tests will be used to determine an air injection/withdrawal rate for the bioventing test. A blower will be selected, installed, and operated for 6 to 12 months, and periodic measurements of the soil gas composition will be made to evaluate the long-term effectiveness of bioventing.

#### 1.2 Site Description

Westover AFB is located in the town of Chicopee north of Springfield, Massachusetts. A schematic diagram of the base is shown in Figure 1. The dashed line on the map represents the direction from the main gate to the test site. The hangar/apron area must be crossed to reach the test site and an escort is required at this point. The site chosen for the bioventing test initiative is located adjacent to Building 7705 and Building 7701 in the pumphouse area (Figure 2). Site investigation activities in the area have indicated soils and groundwater are contaminated with JP-4 jet fuel, with soil TPH concentrations above 2,000 ppm. The sources of contamination are the historic activities in the fuel hydrant area and a JP-4 fuel spill during Desert Shield activities.

Groundwater generally is encountered at 12 to 15 feet below ground surface. Soils at the site consist of fine sand to approximately 5 feet below ground surface, fine to medium sand to 15 feet below ground surface, and fine sand with trace silt to 20 feet below ground surface. A detailed description is provided in the Test Plan in Appendix A.

#### 2.0 CHRONOLOGY OF EVENTS AND SITE ACTIVITIES

#### 2.1 Groundwater Measurements

One groundwater monitoring well (MW-10) was measured at Buildings 7701 and 7705 Site. Groundwater level was recorded at 15 feet during October. Product was measured at 0.3 foot.

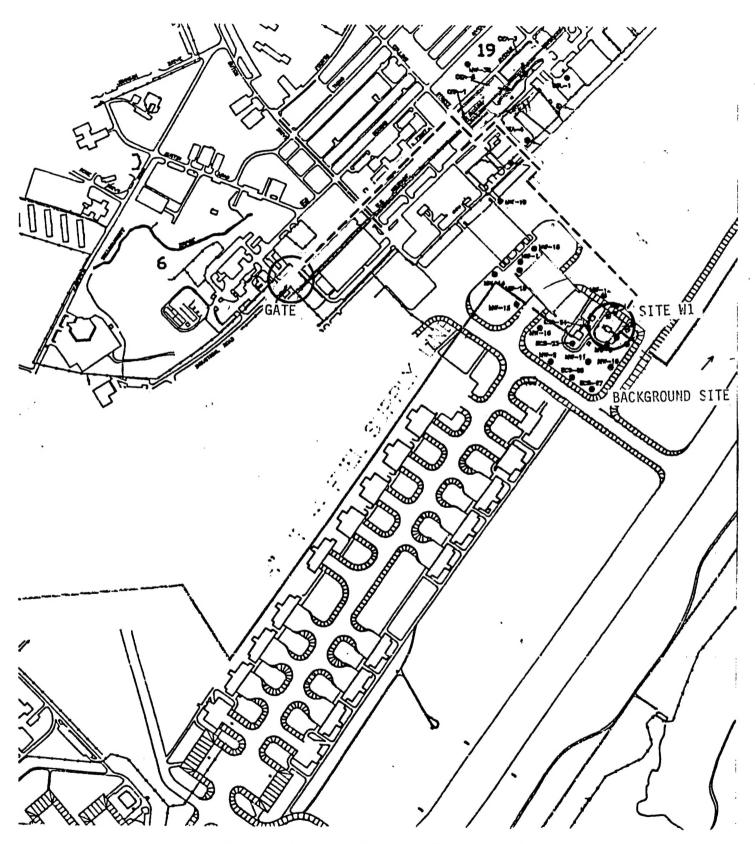

Figure 1. Schematic Diagram of Westover AFB

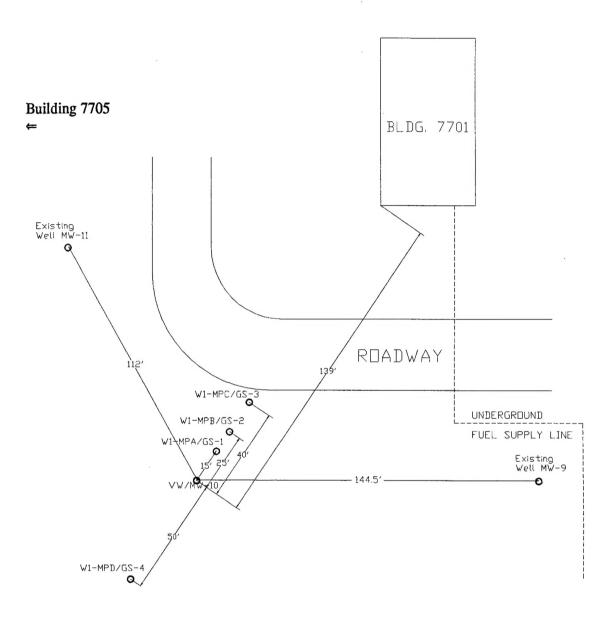

Figure 2. Schematic Diagram of Buildings 7701 and 7705 Site at Westover AFB (GS - Soil Gas Survey Point; MP - Monitoring Point)

#### 2.2 Soil Gas Survey

A suitable site for the bioventing demonstration should have soil gas characteristics of high TPH, low oxygen, and high carbon dioxide concentrations. This composition of soil gas would indicate that oxygen-limiting conditions for microbial activity are present and that the introduction of air may enhance biodegradation of TPH.

On October 20, 1992, a limited soil gas survey was conducted at Buildings 7701 and 7705 Site. Soil gases were sampled by driving with a hammer drill sacrificial points which consisted of ¼-inch tubing with an aluminum, 4-inch screened area. Soil gas was withdrawn with a vacuum pump and analyzed for oxygen, carbon dioxide, and TPH.

Measurements of oxygen and carbon dioxide in the soil gas were made with a GasTech Model 32520X with oxygen and carbon dioxide ranges of 0 to 25%. The analyzer was calibrated daily against atmospheric oxygen, atmospheric carbon dioxide, a 10% oxygen calibration standard, and a 5% carbon dioxide calibration standard. TPH was measured with a GasTech Trace Techtor with TPH ranges from 0 to 100, 0 to 1,000, and 0 to 10,000 ppm. The GasTech Trace Techtor was calibrated daily against a 4,200-ppm hexane standard.

The soil gas probes were driven to depths ranging from 2.5 to 15 feet at several locations (Figure 2) at Buildings 7701 and 7705 Site. Table 1 provides the initial concentrations of oxygen, carbon dioxide, and TPH for the various locations at Buildings 7701 and 7705 Site. Oxygen concentrations varied from 0 to 4.2%, while TPH concentrations ranged from 7,200 ppm to greater than 40,000 ppm. The oxygen concentrations in the soil gas indicate that this site is oxygen-limited and will likely respond to bioventing.

#### 2.3 Vent Well, Monitoring Point, and Thermocouple Installation

An existing monitoring well (MW-10) was used for the vent well at this site. The vent well was 30 feet deep and was screened from 12 to 30 feet.

On October 20, 1992, three three-level and one one-level monitoring points were installed. The monitoring points (MP) were labelled as follows: W1-MPA; W1-MPB; W1-MPC; and W1-MPD. The sacrificial points used for the soil gas survey were used as the monitoring points. The locations of the vent well and monitoring points are shown in Figure 2. A cross section of the vent well and monitoring points showing site lithology and construction detail is shown in Figure 3.

Table 1. Initial Soil Gas Composition at Buildings 7701 and 7705 Site

Soil Gas Survey (GS) Point	Depth (ft)	Oxygen (%)	Carbon Dioxide (%)	TPH (ppm)
GS-1	2.5	0.8	13.0	7,200
	5.0	0.8	13.5	7,200
	7.5	0.5	13.5	9,600
	10.0	0.5	13.5	12,400
	12.5	0.5	14.0	17,600
	14.0	4.21	12.0	17,600
	15.0	ND	ND	ND
GS-2	2.5	0.2	13.0	15,000
	5.0	0.5	13.0	16,400
	7.5	0.5	13.5	18,000
	10.0	0.5	13.0	19,200
	12.5	0.0	13.5	36,800
GS-3	5.0	0.5	12.5	35,600
	10.0	1.5	12.0	37,600
	12.5	1.3	12.3	>40,000

ND No data collected. Groundwater was encountered at this depth.

Pressure reading on sampling pump was high. Measured oxygen concentration may not be representative of actual soil gas oxygen concentrations. Actual oxygen concentration is likely to be lower.

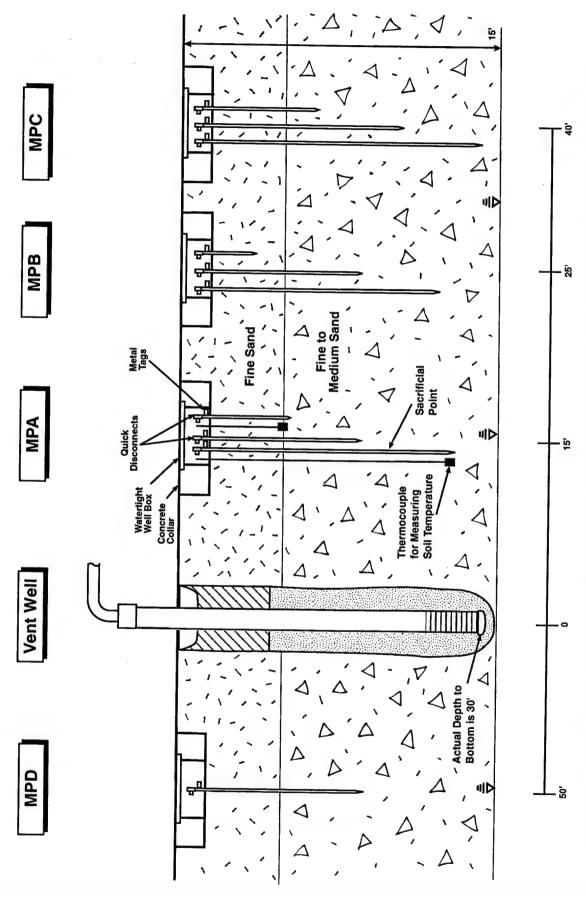

Figure 3. Cross Section of Vent Well and Monitoring Points at Buildings 7701 and 7705 Site Showing Site Lithology and Construction Detail (not to scale)

F/Kitte/W-1

Soil gas probes were sacrificial points which consisted of ¼-inch tubing with an aluminum, 4-inch screened area. No soil borings were created nor was any sand added. A small amount of wetted bentonite was added at the surface. The monitoring points were installed at depths as follows:

- Monitoring point W1-MPA was installed at the following three depths: 4.5,
   8.5, and 13.5 feet.
- Monitoring point W1-MPB was installed at the following depths: 3.5, 8.5, and 12.5 feet.
- Monitoring point W1-MPC was installed at the following depths: 6.5, 10.5, and 14.5 feet.
- Monitoring point W1-MPD was installed at a depth of 9.0 feet.

A Type J thermocouple was installed with monitoring points W1-MPA-4.5' and W1-MPA-13.5'.

#### 2.4 Soil and Soil Gas Sampling and Analyses

Soil samples were collected near the vent well by hand auger. The soil samples were collected at depths of 9.0 to 9.5 feet and 12 to 12.5 feet, with two samples collected at each depth. The soil samples were labelled W1-EX-9 and W1-EX-9'-9.5' for the 9.0 to 9.5 feet depth and W1-EX-12 and W1-EX-12'-12.5' for the 12 to 12.5 feet depth. The samples were sent under chain of custody to Engineering-Science Inc., Berkeley Laboratory for analysis of benzene, toluene, ethylbenzene, and xylenes (BTEX); TPH; alkalinity; moisture content; pH; iron; total phosphate; total Kjeldahl nitrogen; and particle size analysis.

Soil vapor samples were not collected at this site during installation, but will be collected in spring 1993.

#### 2.5 Soil Gas Permeability and Radius of Influence

A detailed description of the method for conducting a soil gas permeability test, including equations to compute k, the soil gas permeability, is given in the Test Plan and Technical Protocol (Hinchee et al., 1992).

Prior to air injection, the monitoring points were allowed to set up for 24 hours. Air was injected with a portable 1-horsepower (HP) explosion-proof positive displacement blower unit. After air injection was initiated, pressure readings were taken approximately every 1 to 2 minutes for the first hour, then approximately every 10 minutes for the following hour. Pressure readings also were collected from monitoring wells MW-9 and MW-11 (Figure 2). The Hyperventilate™ computer model was used to calculate the soil gas permeability.

#### 2.6 In Situ Respiration Test

Immediately following the soil gas permeability test, air containing approximately 1% helium was injected into the soil for approximately 24 hours, beginning on October 27. Air was injected concurrently into the background monitoring well to measure the natural biodegradation of organic material in the soil. The setup for the in situ respiration test is described in the Test Plan and Technical Protocol (Hinchee et al., 1992). The pump used for air injection was a ½-HP diaphragm pump. Air and helium were injected through the following monitoring points at the depths indicated: W1-MPA-8.5'; W1-MPA-13.5'; W1-MPB-8.5'; and W1-MPB-12.5'. After the air/helium injection was turned off, the respiration gases were monitored periodically. The respiration test was terminated on October 30.

Helium concentrations were measured during the in situ respiration test to quantify helium leakage to or from the surface around the monitoring points. Helium loss over time is attributed to either diffusion or leakage. A rapid drop in helium concentration followed by a leveling is an indication of leakage. A gradual loss along with an apparent first-order curve is an indicator of diffusion. As a rough estimate, the diffusion of gas molecules is inversely proportional to the square root of the molecular weight of the gas. Based on molecular weights of 4 for helium and 32 for oxygen, helium gas diffuses about 2.8 times faster than oxygen, or the diffusion of oxygen is 0.35 times the rate of helium diffusion. As a general rule, we have found that if helium concentrations are at least 50 to 60% of the initial levels at test completion, measured oxygen uptake rates are representative. Greater helium loss indicates a problem, and oxygen utilization rates are not considered representative.

To compare data from one site to another, a stoichiometric relationship of the oxidation of the hydrocarbon was assumed. Hexane was used as the representative hydrocarbon for the organic contaminant. The stoichiometric relationship is given by:

$$C_6H_{14} + 9.5O_2 - 6CO_2 + 7H_2O$$
 (1)

Based on the utilization rates (% per day), the biodegradation rates in terms of milligrams as a hexane equivalent per kilograms of soil per day were computed using the equation below by assuming a soil porosity of 0.2 and a bulk density of 1,440 kg/m<sup>3</sup>.

$$K_{\beta} = \frac{-K_o A D_o C}{100}$$
 (2)

where:  $K_{f}$  = biodegradation rate (mg/kg/day)

 $K_0$  = oxygen utilization rate (percent per day)

A = volume of air/kg of soil, in this case 300/1,440 = 0.21

 $D_0$  = density of oxygen gas (mg/L) assumed to be 1,330 mg/L

C = mass ratio of hydrocarbon to oxygen required for mineralization, assumed to be 1:3.5 from the stoichiometric equation.

#### 3.0 RESULTS AND DISCUSSION

#### 3.1 Soil and Soil Gas Analyses

Results of the soil analyses for BTEX and TPH are presented in Table 2. The results of the soil chemistry analyses are summarized in Table 3. The analytical report for this site is presented in Appendix B. Although a hydrocarbon odor was detected at the time of collection of the soil samples, none of the BTEX compounds or TPH were detected in the soil samples. It seems unlikely that there is no soil contamination at the site, based upon the soil gas survey where relatively high concentrations of TPH were detected in soil gas. It may be necessary to collect an additional soil sample from this site, in case the lack of BTEX compounds or TPH in the soil samples was due to

Table 2. Results From Soil Analysis for BTEX and TPH at Buildings 7701 and 7705 Site

	Clay:	1.5	Clay:	1.5		

sampling or laboratory error. However, it also is possible that the samples were collected from an area of low contamination, although the majority of the site may be contaminated.

#### 3.2 Soil Gas Permeability and Radius of Influence

The raw data for the soil gas permeability test at Buildings 7701 and 7705 Site are presented in Appendix C. Using the Hyperventilate<sup>11</sup> computer model, soil gas permeabilities were calculated at each of the monitoring points. These data are presented in Table 4. The soil gas permeability values were relatively consistent except at one point where pressure changes could not be detected. Soil gas permeability values ranged 510,000 darcy up to 3.2 x 10<sup>10</sup> darcy. The radius of influence is calculated by plotting the log of the pressure change at a specific monitoring point versus the distance from the vent well. The radius of influence would then be the distance where 1 inch of water pressure can be measured. Therefore, the radius of influence based on these specifications was approximately 6 feet (Figure 4).

#### 3.3 In Situ Respiration Test

The results of the in situ respiration test for Buildings 7701 and 7705 Site are presented in Appendix D. Each figure in Appendix D illustrates the oxygen, carbon dioxide, and helium concentrations as a function of time. An example of typical oxygen utilization at this site is shown in Figure 5, where oxygen utilization and carbon dioxide production at monitoring point W1-MPB-12.5' are illustrated. A summary of the oxygen utilization and carbon dioxide production rates and corresponding biodegradation rates is shown in Table 5. The biodegradation rates measured at this site were relatively high, with rates ranging from 4.4 mg/kg/day to 9.6 mg/kg/day based upon oxygen utilization, and from 2.6 mg/kg/day to 3.7 mg/kg/day based upon carbon dioxide production.

Loss of helium was insignificant at all monitoring points, indicating that the monitoring points were well sealed and that the oxygen depletion observed was a result of biodegradation.

Soil temperatures were measured during the in situ respiration test. Temperatures during the test ranged from 12.7°C to 13.3°C at monitoring point W1-MPA-4.5′ and from 15.3°C to 15.6°C at monitoring point W1-MPA-13.5′.

Table 4. Results of Hyperventilate™ Soil Gas Permeability Analysis at Buildings 7701 and 7705 Site

Monitoring Point <sup>1</sup>	Depth (ft)	Soil Gas Permeability (darcy)
W1-MPA	4.5	4.3 x 10°
	8.5	3.2 x 10 <sup>10</sup>
	13.5	510,000
W1-MPB	3.5	1.6 x 10°
	8.5	1.3 x 10°
	12.5	2.6 x 10 <sup>8</sup>
W1-MPC	6.5	1.2 x 10 <sup>8</sup>
	10.5	4.2 x 10 <sup>7</sup>
	14.5	NR
W1-MPD	9.0	3.4 x 10 <sup>8</sup>

Hyperventilate could not be calculated for data from MW-9 and MW-11, because measurements could not be taken until 30 minutes into the test.

NR No pressure readings were detected at this monitoring point.

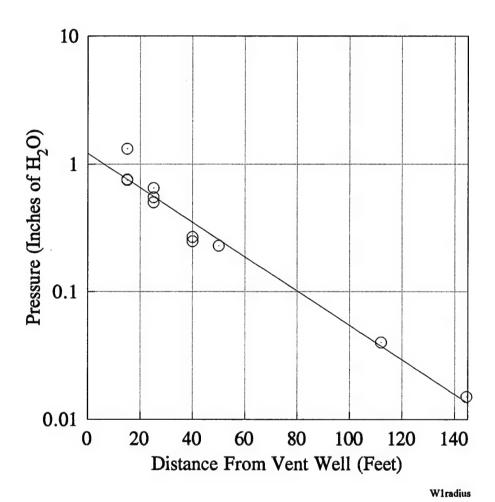

Figure 4. Radius of Influence at Buildings 7701 and 7705 Site

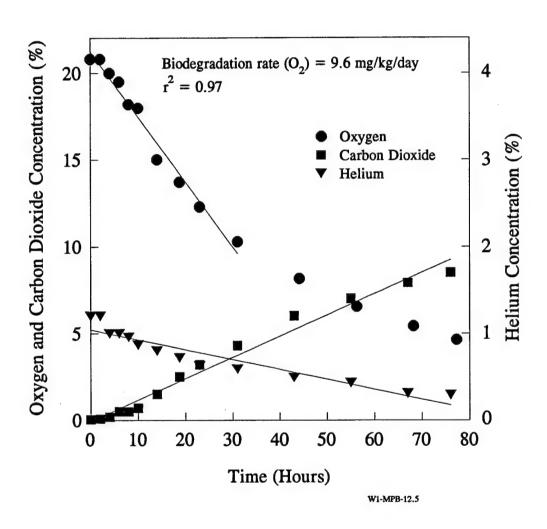

Figure 5. Oxygen Utilization and Carbon Dioxide Production During the In Situ Respiration Test at Monitoring Point W1-MPB-12.5'

Table 5. Oxygen Utilization and Carbon Dioxide Production Rates During the In Situ Respiration Test at Buildings 7701 and 7705 Site

Monitoring Point	Oxygen Utilization Rate (%/hour)	Biodegradation Rate (mg/kg/day)	Carbon Dioxide Production Rate (%/hour)	Biodegradation Rate (mg/kg/day)
Background	0.012	0.23	0.010	0.22
W1-MPA-8.5'	0.23	4.4	0.15	3.2
W1-MPA-13.5'	0.25	4.8	0.12	2.6
W1-MPB-8.5'	0.34	6.5	0.17	3.7
W1-MPB-12.5'	0.50	9.6	0.15	3.2

#### 3.4 Bioventing Demonstration

The decision was made to install a bioventing system at Buildings 7701 and 7705 Site. A 1-HP blower was installed at the site. Air injection has not been initiated at the site to date due to lack of electrical supply. The electricity is to be supplied by the base.

#### 4.0 BACKGROUND AREA ACTIVITIES

An existing monitoring well (MW-36) was used as the background vent well. The existing vent well is located approximately 600 feet northeast from the vent well in the contaminated area (Figure 1) and is 20 feet deep and is screened from 10 feet to 20 feet. Groundwater was measured in the well at approximately 14.5 feet. Site lithology at this area was representative of that in the contaminated areas.

An in situ respiration test was conducted at the background area beginning on October 28 after 24 hours of air injection. The test was concluded on October 31. Very little decrease in oxygen concentration occurred during the course of the in situ respiration test (Figure 6).

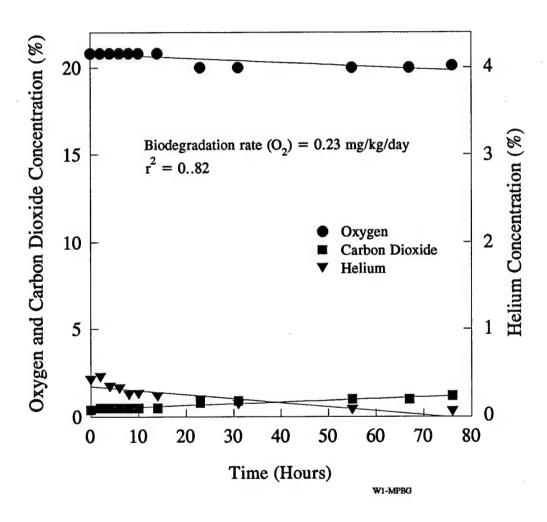

Figure 6. Oxygen Utilization and Carbon Dioxide Production During the In Situ Respiration Test at the Background Area

#### 5.0 FUTURE WORK

Once the bioventing system is operating, base personnel will be required to perform a simple weekly system check to ensure that the blower is operating within its intended flowrate, pressure, and temperature range. An on-site briefing for base personnel who will be responsible for blower system checks will be conducted when the blowers are operational. The principle of operation will be explained, and a simple checklist and logbook will be provided for blower data. Base personnel will be asked to perform minor maintenance activities, such as replacing filters or gauges, or draining condensate from knockout chambers, but they will not be expected to perform complicated repairs or analyze gas samples. Replacement filters and gauges will be provided and shipped to the base, and serious problems, such as motor or blower failures, will be corrected by Battelle.

The progress of this system will be monitored by conducting semiannual respiration tests in the vent well and in each monitoring point and by regularly measuring the oxygen, carbon dioxide, and hydrocarbon concentrations in the extracted soil gas and comparing them to background levels. At least twice each year, the progress of the bioventing test will be reported to the base point-of-contact.

Test Plan and Technical Protocol for a Field Treatability Test for Bioventing (Rev. 2), Report prepared by Battelle Columbus Operations, U.S. Air Force Center for Environmental Excellence, and Engineering Sciences, Inc. for the U.S. Air Force Center for Environmental Excellence, Brooks Air Force Base, Texas.

# APPENDIX A

TEST PLAN FOR WESTOVER AFB, MASSACHUSETTS

505 King Avenue Columbus, Ohio 43201-2693 Telephone (614) 424-6424 Facsimile (614) 424-5263

October 1, 1992

Capt. Catherine Vogel
Department of the Air Force
Building 1117
HQ AFESC/RDVW
Tyndall AFB, Florida 32403-6001

Dear Cathy:

# SUBJECT: TEST PLAN FOR BIOVENTING INITIATIVE FIELD TEST AT WESTOVER AFB, MA.

This letter was prepared to accompany the report "Test Plan and Technical Protocol for a Field Treatability Test for Bioventing." The protocol document was developed as a generic test plan for the Air Force Bioventing Initiative Project in which Westover AFB is participating. This letter outlines site specific information to support the generic test plan.

The site anticipated for the bioventing test initiative is Building 7705 in the pumphouse apron area (see figure 1 for site map). This site is known to be contaminated with JP-4 jet fuel with soil TPH concentrations above 2000 ppm. The sources of contamination are the historic activities in the fuel hydrant area and a JP-4 fuel spill during Desert Shield activities.

The purpose of this project is to investigate the feasibility of using the bioventing technology to remediate petroleum contaminated soils at the above mentioned facility.

## Site Description-

Building 7705 is located in the fuel pumphouse area. The test site for the Bioventing Initiative is located adjacent to Building 7705 and Building 7701. Site investigation activities in the area have indicated soils and groundwater are contaminated with JP-4 jet fuel (see Table 1). Groundwater is generally encountered at 12 to 15 ft below ground surface (bgs). Soils at the site consist of fine sand to approximately 5 ft bgs, fine to medium sand to 15 bgs, and fine sand with trace silt to 20 bgs. The approximate location of monitoring wells ECS-26 and ECS-24 have been drawn on Figure 1. ECS-26 is a likely candidate for use as the bioventing vent well. The soil boring log for ECS-26 is presented in Figure 3.

#### Project activities-

The following field activities are planned for the bioventing project at Westover AFB. Additional detail can be found in Section 5.0 of the generic test plan and technical protocol.

1- A small scale soil gas survey will be conducted to identify an appropriate location for installation of the bioventing system. Soil vapor from the candidate site must exhibit high petroleum hydrocarbon concentrations (10,000 ppm or greater), relatively low O<sub>2</sub> concentrations (0 % to 2.0 %), and relatively high CO<sub>2</sub> concentrations (depending on soil type, 2.0 % to 10.0 %). There are four monitoring wells in the area of Building 7705 (ECS-26, ECS-24, MW-11, and MW-12) that appear to be good candidates for use as bioventing wells. The soil gas survey will be concentrated around these wells.

An uncontaminated background location will also be identified using soil gas survey techniques.

Once the installation site is located, one vent well and three 3-level soil gas monitoring points will be installed in the contaminated location and one vent well will be installed in the background area. The existing monitoring wells will be evaluated for use as the bioventing air injection well. If none of the existing wells are suitable for use as the bioventing well, a trailer mounted drill rig with solid or hollow stem auger will be used to bore down to just above the water table and install a 2-inch vent well. Three to four soil samples will be collected for chemical/physical analysis.

Sacrificial drive points will be used for the permanent (three-level) soil gas monitoring points, if possible. Otherwise, the three-level points will be installed using the portable drill rig.

- 3- The air permeability test will be conducted in the contaminated test location.
- 4- Following the air permeability test, in situ respiration tests will be conducted in both the contaminated and the background test locations.
- Depending on the results of the air permeability test and the in situ respiration test, a decision will be made whether or not to install a blower system in the contaminated area for the long term bioventing test. If the decision is made to install, the blower will be plumbed to the vent well and bioventing will be started (assuming power is available). Site personnel will be trained for blower operation prior to Battelle leaving the site.

#### Schedule-

Field activities at Westover AFB are planned to begin on October 19, 1992. Battelle will have 2 to 3 people on site for approximately 2 weeks.

#### Base Support-

Westover AFB needs to be able to provide the following:

- Digging permits and utility clearance for all sites need to be obtained prior to the initiation of the field work. Underground utilities should be clearly marked to reduce the chance of utility damage or personal injury during soil gas probe and well installation. Battelle will not be able to begin field operations without these clearances.
- Electrical power will need to be easily accessible from the project site. The air permeability test and in situ respiration test can be performed using a gasoline powered electric generator. The operation of the bioventing system will require a permanent 220/110 V power source. If power will not be available immediately after the test is completed the bioventing system will be installed for start-up at a later date.
- Regulatory approval, if any is required, will need to be obtained by the base prior to start-up of the bioventing system. The system will likely be configured for air injection so there will be no point source vapor emission from the system. The wells to be installed will not intersect the apparent water table and no groundwater will be pumped.
- Drums for containment of contaminated soil cuttings. The base will be responsible for disposal of any contaminated soils.
- Site specific safety information will be needed for incorporation into Battelle's Health and Safety Plan. This information includes: emergency phone numbers for ambulance, fire department, security, etc....
- Base and site clearance will be required for Battelle's site employees. We will furnish the base POC with personal information for each person at least one week prior to starting field operations.

October 1, 1992

Thank you for your support for this bioremediation research project. If you have any questions please feel free to call me at (614) 424-6122.

Sincerely,

Jeffrey A. Kittel

#### REMARKS

- Field testing values represent total volatile organic compound vapor levels (referenced to a benzene standard)
  measured in the head space of sealed soil sample jars with an HNu Model PI Photoionization Meter. Results reported
  in parts per million (ppm). Detection Limit = 0.2 ppm. BDL = Below Detection Limit.
- 2. Encountered groundwater at approximately 14.
- 3. Installed 2" PVC monitoring well at 20' using 10' slotted screen and 10' solid riser. Sand pack to 7'; bentonite seal to 6'; natural fill to 0.5'; cement at surface with 2' stick-up lock.
- 4. Jet fuel odor throughout boring.

Work Order No.:4494

Client:

Jeff Kittel Battelle

505 Kings Ave. Columbus, OH 43201

Date of Sample Receipt: 10/30/92

Your soil samples identified as:

W1-EX-9 W1-EX-12

were analyzed for pH, alkalinity, iron, moisture, total Kjeldahl nitrogen, total phosphorus and soil classification.

Finally your soil samples identified as:

W1-EX-9'-9.5' W1-EX-12'-12.5'

were analyzed for BTEX by EPA Method 8020 and TRPH by EPA Method 418.1.

The analytical reports for the samples listed above are attached.
